Areas

- The area under a curve $y = F(x)$ from a to b is

$$A = \int_a^b F(x)\mathrm{d}x$$

- Suppose the curve has parametric equations $x = f(t)$, $y = g(t)$, $\alpha \leq t \leq \beta$.
- Then use the Substitution Rule to find the area:

$$A = \int_a^b y\mathrm{d}x = \int_\alpha^\beta g(t)f'(t)\mathrm{d}t$$

- How do we know where to put α and β?
- When $x = a$, t will be either α or β. When $x = b$, t will take the other value.

Example

Find the area under one arch of the cycloid

$$x = r(\theta - \sin\theta), \qquad y = r(1 - \cos\theta)$$
One arch is given by $0 \leq \theta \leq 2\pi$.

$$
\begin{aligned}
A &= \int_0^{2\pi r} y \, \mathrm{d}x = \int_0^{2\pi} r(1 - \cos\theta) r(1 - \cos\theta) \mathrm{d}\theta \\
&= r^2 \int_0^{2\pi} (1 - \cos\theta)^2 \mathrm{d}\theta = r^2 \int_0^{2\pi} (1 - 2\cos\theta + \cos^2\theta) \mathrm{d}\theta \\
&= r^2 \int_0^{2\pi} \left(1 - 2\cos\theta + \frac{1}{2}(1 + \cos 2\theta) \right) \mathrm{d}\theta \\
&= r^2 \left[\frac{3}{2}\theta - 2\sin\theta + \frac{1}{4}\sin 2\theta \right]_0^{2\pi} = r^2 \left(\frac{3}{2} \cdot 2\pi \right) = 3\pi r^2
\end{aligned}
$$

Areas in Polar Coordinates

Suppose we have a polar curve $r = f(\theta)$, $a \leq \theta \leq b$.
Definition

We say that the figure obtained as the union of the segments connecting the origin with the points of the curve is the figure *swept* by the curve as θ varies from *a* to *b*.

$r = f(\theta)$

Theorem

Suppose no two points on the curve lie on the same ray from the origin. Then the area swept by the curve equals $A = \displaystyle\int_a^b \frac{1}{2} \left(f(\theta)\right)^2 \, \mathrm{d}\theta$.
Area swept by a polar curve: justification

Split $[a, b]$ into N equal segments via points $a = \theta_0 \leq \theta_1 \leq \cdots \leq \theta_{N-1} \leq \theta_N = b$. The length of each segment is $\Delta = \frac{b-a}{N}$. Let $r_i = f(\theta_i)$. Then each θ_i gives a point P_i with polar coordinates (r_i, θ_i).

The area swept by the curve is approximated by sum of areas of triangles given by connecting the origin with two consecutive vertices. Consider one such triangle, say, OP_1P_2. By Euclidean geometry, the area of $\triangle OP_1P_2$ is $\frac{|OP_1||OP_2|\sin\Delta}{2} = \frac{r_1 r_2 \sin\Delta}{2} = \frac{f(\theta_1)f(\theta_2)\sin\Delta}{2}$.

Area swept by a polar curve: justification

Split $[a, b]$ into N equal segments via points $a = \theta_0 \leq \theta_1 \leq \cdots \leq \theta_{N-1} \leq \theta_N = b$. The length of each segment is $\Delta = \frac{b-a}{N}$. Let $r_i = f(\theta_i)$. Then each θ_i gives a point P_i with polar coordinates (r_i, θ_i).

Therefore the area swept by the curve equals the limit of the sum:

$$
\begin{aligned}
A &= \lim_{\Delta \to 0} \sum_{i=0}^{N-1} \frac{f(\theta_i)f(\theta_{i+1})\sin\Delta}{2} = \lim_{\Delta \to 0} \frac{\sin\Delta}{\Delta} \sum_{i=0}^{N-1} \frac{f(\theta_i)f(\theta_i+\Delta)\Delta}{2} \\
\text{(can be proved)} \quad &= \lim_{\Delta \to 0} \frac{\sin\Delta}{\Delta} \lim_{\Delta \to 0} \sum_{i=0}^{N-1} \frac{f(\theta_i)f(\theta_i+\Delta)\Delta}{2} = 1 \cdot \lim_{\Delta \to 0} \sum_{i=0}^{N-1} \frac{f(\theta_i)f(\theta_i)\Delta}{2} \\
\text{(Riemann sum)} \quad &= \lim_{\Delta \to 0} \sum_{i=0}^{N-1} \frac{f^2(\theta_i)\Delta}{2} = \int_a^b \frac{f^2(\theta)}{2} d\theta
\end{aligned}
$$

Example

Find the area enclosed by one loop of the four-leaved rose $r = \cos 2\theta$.

$r = \cos(2\theta)$
$\theta = \frac{\pi}{4}$

$\theta = -\frac{\pi}{4}$

The region enclosed by the right loop corresponds to points whose θ polar coordinate lies in the interval $-\frac{\pi}{4} \leq \theta \leq \frac{\pi}{4}$.

$$
\begin{aligned}
A &= \int_{-\frac{\pi}{4}}^{\frac{\pi}{4}} \frac{1}{2} r^2 \mathrm{d}\theta \\
&= \frac{1}{2} \int_{-\frac{\pi}{4}}^{\frac{\pi}{4}} \cos^2(2\theta) \mathrm{d}\theta \\
&= \int_{0}^{\frac{\pi}{4}} \cos^2(2\theta) \mathrm{d}\theta \\
&= \int_{0}^{\frac{\pi}{4}} \frac{1}{2}(1 + \cos(4\theta)) \mathrm{d}\theta \\
&= \frac{1}{2} \left[\theta + \frac{1}{4}\sin(4\theta) \right]_{0}^{\frac{\pi}{4}} \\
&= \frac{\pi}{8}
\end{aligned}
$$

Example

Find all points of intersection of the polar curves $r = \frac{1}{2}$ and $r = \cos(2\theta)$.

$$
\begin{aligned}
\cos 2\theta &= \frac{1}{2} \\
2\theta &= \frac{\pi}{3}, \frac{5\pi}{3}, \frac{7\pi}{3}, \frac{11\pi}{3} \\
\theta &= \frac{\pi}{6}, \frac{5\pi}{6}, \frac{7\pi}{6}, \frac{11\pi}{6}
\end{aligned}
$$

- This only gives four points.
- There are actually eight.
- The circle $r = \frac{1}{2}$ also has polar equation $r = -\frac{1}{2}$.
- To find all eight points, solve $\cos(2\theta) = \frac{1}{2}$ and $\cos(2\theta) = -\frac{1}{2}$.

$r = \frac{1}{2}$

$r = \cos(2\theta)$

Example

Find the area that lies within the circle $r = 3 \sin \theta$ and outside of the cardioid $r = 1 + \sin \theta$.

The curves meet if

$$3 \sin \theta = 1 + \sin \theta$$
$$\sin \theta = \frac{1}{2}$$
$$\theta = \frac{\pi}{6}, \ \frac{5\pi}{6}$$

$$A = \frac{1}{2} \int_{\frac{\pi}{6}}^{\frac{5\pi}{6}} (3 \sin \theta)^2 \mathrm{d}\theta - \frac{1}{2} \int_{\frac{\pi}{6}}^{\frac{5\pi}{6}} (1 + \sin \theta)^2 \mathrm{d}\theta$$

$$= \frac{1}{2} \int_{\frac{\pi}{6}}^{\frac{5\pi}{6}} \left(9 \sin^2 \theta - (1 + 2 \sin \theta + \sin^2 \theta) \right) \mathrm{d}\theta$$

$$= \frac{1}{2} \int_{\frac{\pi}{6}}^{\frac{5\pi}{6}} \left(8 \sin^2 \theta - 1 - 2 \sin \theta \right) \mathrm{d}\theta$$

$$= \int_{\frac{\pi}{6}}^{\frac{\pi}{2}} \left(8 \sin^2 \theta - 1 - 2 \sin \theta \right) \mathrm{d}\theta$$

$$= \int_{\frac{\pi}{6}}^{\frac{\pi}{2}} \left(3 - 4 \cos 2\theta - 2 \sin \theta \right) \mathrm{d}\theta$$

$$= \left[3\theta - 2 \sin 2\theta + 2 \cos \theta \right]_{\frac{\pi}{6}}^{\frac{\pi}{2}}$$

$$= \left(3\frac{\pi}{2} - 2 \cdot 0 + 2 \cdot 0 \right) - \left(3\frac{\pi}{6} - 2\frac{\sqrt{3}}{2} + 2\frac{\sqrt{3}}{2} \right)$$

$$= \pi$$
